“The Class That Gives CMU Its Zip!”

Bits and Bytes

Aug. 29, 2002

Topics

- **Why bits?**
- **Representing information as bits**
 - **Binary/Hexadecimal**
 - **Byte representations**
 - » **numbers**
 - » **characters and strings**
 - » **Instructions**
- **Bit-level manipulations**
 - **Boolean algebra**
 - **Expressing in C**

Why Don't Computers Use Base 10?

Base 10 Number Representation

- That's why fingers are known as "digits"
- Natural representation for financial transactions
 - Floating point number cannot exactly represent \$1.20
- Even carries through in scientific notation
 - 1.5213×10^4

Implementing Electronically

- Hard to store
 - ENIAC (First electronic computer) used 10 vacuum tubes / digit
- Hard to transmit
 - Need high precision to encode 10 signal levels on single wire
- Messy to implement digital logic functions
 - Addition, multiplication, etc.

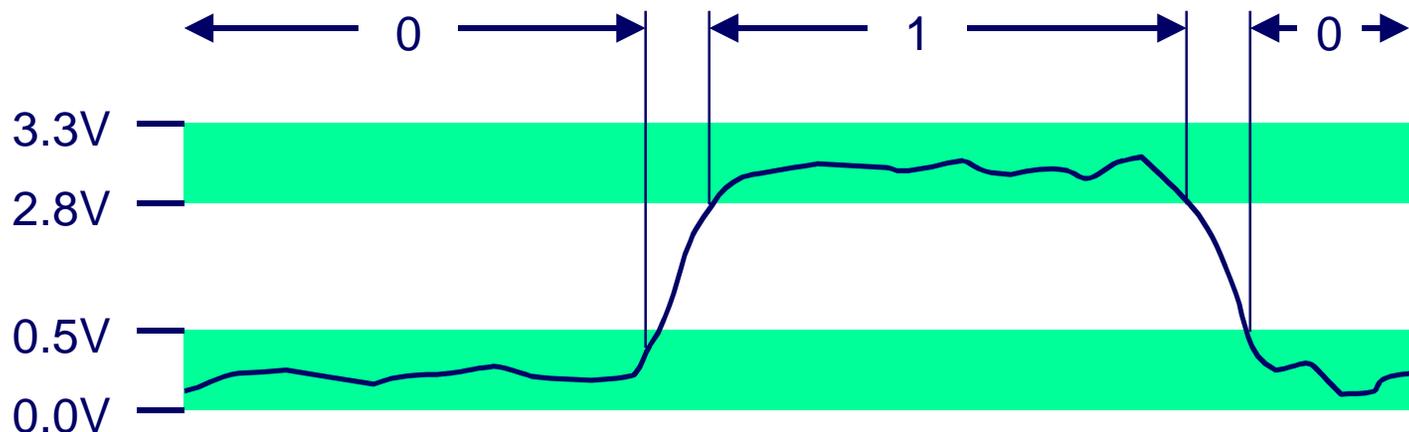

Binary Representations

Base 2 Number Representation

- Represent 15213_{10} as 11101101101101_2
- Represent 1.20_{10} as $1.0011001100110011[0011]..._2$
- Represent 1.5213×10^4 as $1.1101101101101_2 \times 2^{13}$

Electronic Implementation

- Easy to store with bistable elements
- Reliably transmitted on noisy and inaccurate wires

Byte-Oriented Memory Organization

Programs Refer to Virtual Addresses

- Conceptually very large array of bytes
- Actually implemented with hierarchy of different memory types
 - SRAM, DRAM, disk
 - Only allocate for regions actually used by program
- In Unix and Windows NT, address space private to particular “process”
 - Program being executed
 - Program can clobber its own data, but not that of others

Compiler + Run-Time System Control Allocation

- Where different program objects should be stored
- Multiple mechanisms: static, stack, and heap
- In any case, all allocation within single virtual address space

Encoding Byte Values

Byte = 8 bits

- Binary 00000000_2 to 11111111_2
- Decimal: 0_{10} to 255_{10}
- Hexadecimal 00_{16} to FF_{16}
 - Base 16 number representation
 - Use characters '0' to '9' and 'A' to 'F'
 - Write $FA1D37B_{16}$ in C as $0xFA1D37B$
 - » Or $0xfa1d37b$

Hex	Decimal	Binary
0	0	0000
1	1	0001
2	2	0010
3	3	0011
4	4	0100
5	5	0101
6	6	0110
7	7	0111
8	8	1000
9	9	1001
A	10	1010
B	11	1011
C	12	1100
D	13	1101
E	14	1110
F	15	1111

Machine Words

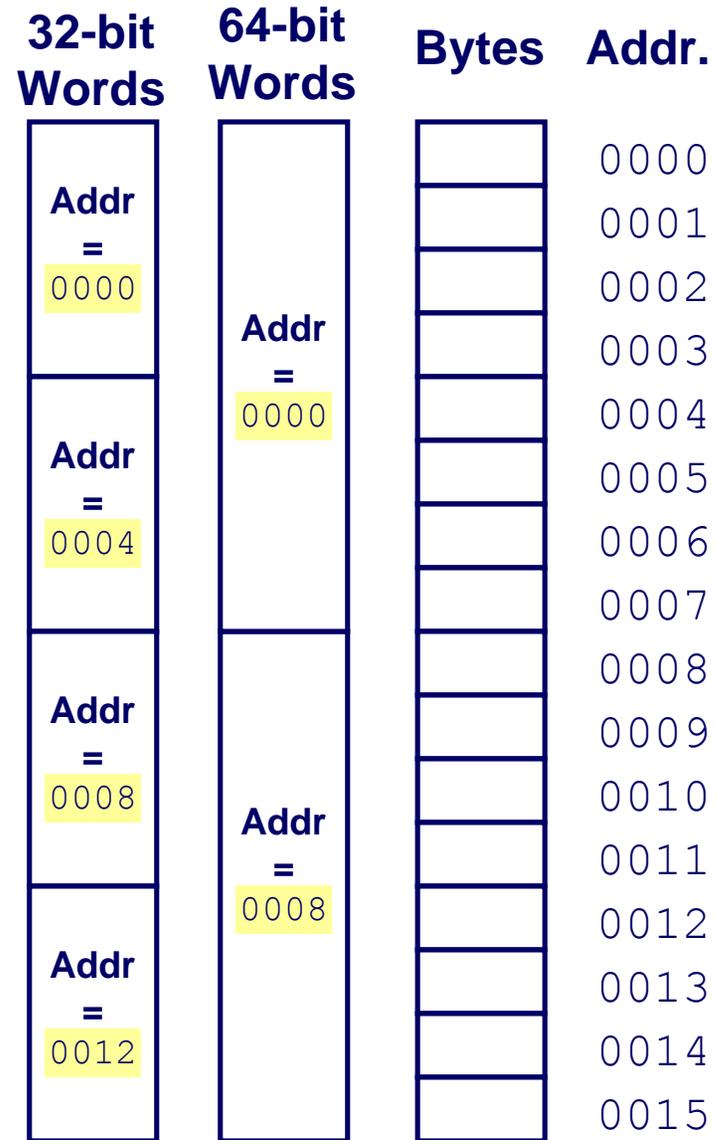

Machine Has “Word Size”

- **Nominal size of integer-valued data**
 - Including addresses
- **Most current machines are 32 bits (4 bytes)**
 - Limits addresses to 4GB
 - Becoming too small for memory-intensive applications
- **High-end systems are 64 bits (8 bytes)**
 - Potentially address $\approx 1.8 \times 10^{19}$ bytes
- **Machines support multiple data formats**
 - Fractions or multiples of word size
 - Always integral number of bytes

Word-Oriented Memory Organization

Addresses Specify Byte Locations

- Address of first byte in word
- Addresses of successive words differ by 4 (32-bit) or 8 (64-bit)

Data Representations

Sizes of C Objects (in Bytes)

■ C Data Type	Compaq Alpha	Typical 32-bit	Intel IA32
● int	4	4	4
● long int	8	4	4
● char	1	1	1
● short	2	2	2
● float	4	4	4
● double	8	8	8
● long double	8	8	10/12
● char *	8	4	4

» Or any other pointer

Byte Ordering

How should bytes within multi-byte word be ordered in memory?

Conventions

- Sun's, Mac's are "Big Endian" machines
 - Least significant byte has highest address
- Alphas, PC's are "Little Endian" machines
 - Least significant byte has lowest address

Byte Ordering Example

Big Endian

- Least significant byte has highest address

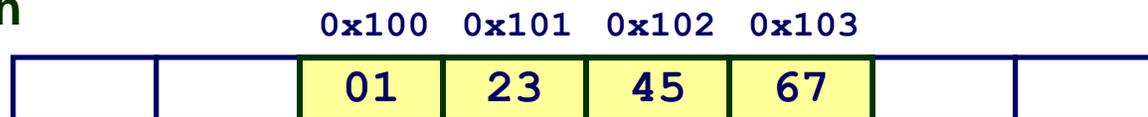

Little Endian

- Least significant byte has lowest address

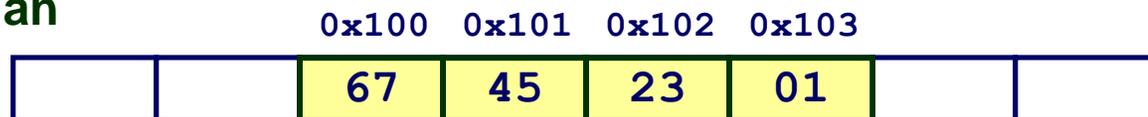

Example

- Variable `x` has 4-byte representation `0x01234567`
- Address given by `&x` is `0x100`

Big Endian

Little Endian

Reading Byte-Reversed Listings

Disassembly

- Text representation of binary machine code
- Generated by program that reads the machine code

Example Fragment

Address	Instruction Code	Assembly Rendition
8048365:	5b	pop %ebx
8048366:	81 c3 <u>ab 12 00 00</u>	add \$0x12ab, %ebx
804836c:	83 bb 28 00 00 00 00	cmpl \$0x0, 0x28 (%ebx)

Deciphering Numbers

- Value: 0x12ab
- Pad to 4 bytes: 0x000012ab
- Split into bytes: 00 00 12 ab
- Reverse: ab 12 00 00

Examining Data Representations

Code to Print Byte Representation of Data

- Casting pointer to unsigned char * creates byte array

```
typedef unsigned char *pointer;

void show_bytes(pointer start, int len)
{
    int i;
    for (i = 0; i < len; i++)
        printf("0x%p\t0x%.2x\n",
              start+i, start[i]);
    printf("\n");
}
```

Printf directives:

%p: Print pointer

%x: Print Hexadecimal

show_bytes Execution Example

```
int a = 15213;
printf("int a = 15213;\n");
show_bytes((pointer) &a, sizeof(int));
```

Result (Linux):

```
int a = 15213;
0x11ffffcb8  0x6d
0x11ffffcb9  0x3b
0x11ffffcba  0x00
0x11ffffcbb  0x00
```

Representing Integers

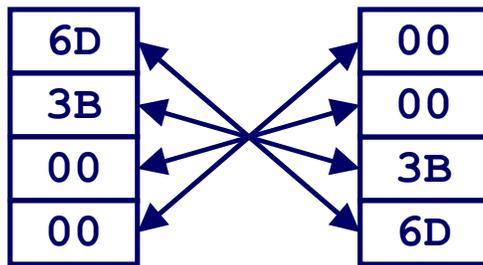

```
int A = 15213;
int B = -15213;
long int C = 15213;
```

Decimal: 15213

Binary: 0011 1011 0110 1101

Hex: 3 B 6 D

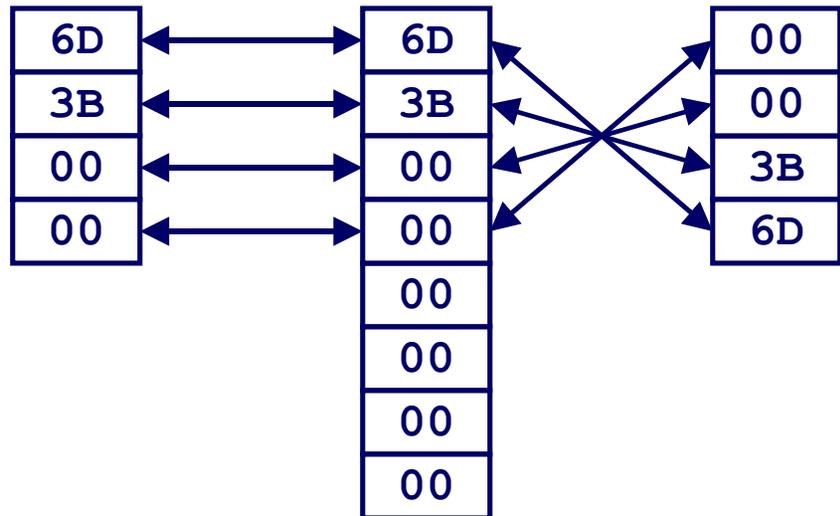

Linux/Alpha A Sun A

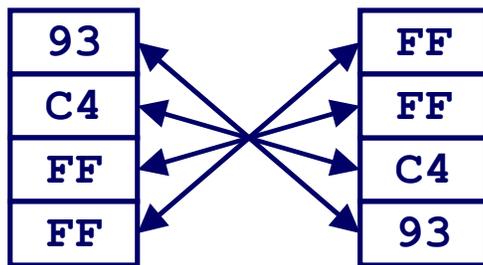

Linux C

Alpha C

Sun C

Linux/Alpha B Sun B

Two's complement representation
(Covered next lecture)

Representing Pointers

```
int B = -15213;
int *P = &B;
```

BF

Different compilers & machines assign different locations to objects

Representing Floats

Float F = 15213.0;

IEEE Single Precision Floating Point Representation								
Hex:	4	6	6	D	B	4	0	0
Binary:	0100	0110	0110	1101	1011	0100	0000	0000
15213:			1110	1101	1011	01		

Not same as integer representation, but consistent across machines

Can see some relation to integer representation, but not obvious

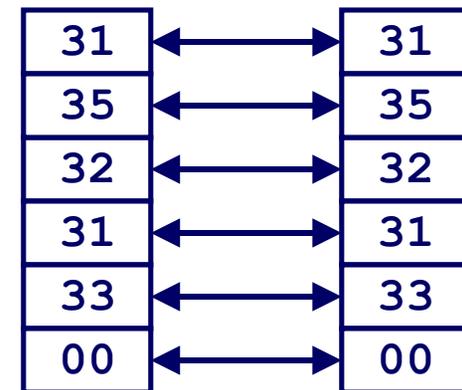

Representing Strings

Strings in C

- Represented by array of characters
- Each character encoded in ASCII format
 - Standard 7-bit encoding of character set
 - Other encodings exist, but uncommon
 - Character “0” has code $0x30$
 - » Digit i has code $0x30+i$
- String should be null-terminated
 - Final character = 0

```
char S[6] = "15213";
```

Linux/Alpha s Sun s

Compatibility

- Byte ordering not an issue
 - Data are single byte quantities
- Text files generally platform independent
 - Except for different conventions of line termination character(s)!

Machine-Level Code Representation

Encode Program as Sequence of Instructions

- Each simple operation
 - Arithmetic operation
 - Read or write memory
 - Conditional branch
- Instructions encoded as bytes
 - Alpha's, Sun's, Mac's use 4 byte instructions
 - » Reduced Instruction Set Computer (RISC)
 - PC's use variable length instructions
 - » Complex Instruction Set Computer (CISC)
- Different instruction types and encodings for different machines
 - Most code not binary compatible

Programs are Byte Sequences Too!

Representing Instructions

```
int sum(int x, int y)
{
    return x+y;
}
```

- For this example, Alpha & Sun use two 4-byte instructions
 - Use differing numbers of instructions in other cases
- PC uses 7 instructions with lengths 1, 2, and 3 bytes
 - Same for NT and for Linux
 - NT / Linux not fully binary compatible

Different machines use totally different instructions and encodings

Boolean Algebra

Developed by George Boole in 19th Century

- Algebraic representation of logic
 - Encode “True” as 1 and “False” as 0

And

- $A \& B = 1$ when both $A=1$ and $B=1$

$\&$	0	1
0	0	0
1	0	1

Or

- $A | B = 1$ when either $A=1$ or $B=1$

	0	1
0	0	1
1	1	1

Not

- $\sim A = 1$ when $A=0$

\sim	
0	1
1	0

Exclusive-Or (Xor)

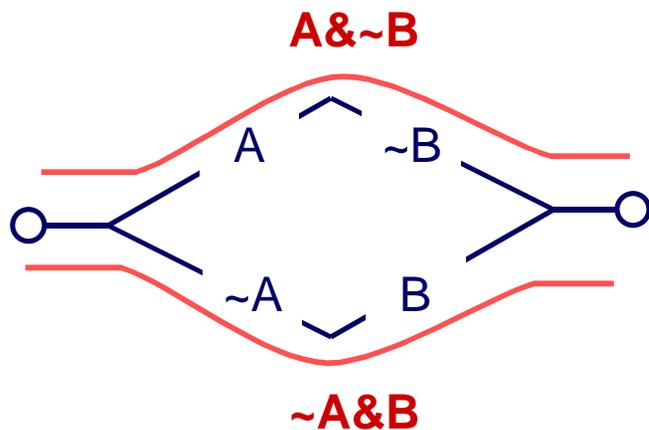

- $A \wedge B = 1$ when either $A=1$ or $B=1$, but not both

\wedge	0	1
0	0	1
1	1	0

Application of Boolean Algebra

Applied to Digital Systems by Claude Shannon

- 1937 MIT Master's Thesis
- Reason about networks of relay switches
 - Encode closed switch as 1, open switch as 0

Connection when

$$A \& \sim B \mid \sim A \& B$$

$$= A \wedge B$$

Integer Algebra

Integer Arithmetic

- $\langle \mathbb{Z}, +, *, -, 0, 1 \rangle$ forms a “ring”
- Addition is “sum” operation
- Multiplication is “product” operation
- $-$ is additive inverse
- 0 is identity for sum
- 1 is identity for product

Boolean Algebra

Boolean Algebra

- $\langle \{0,1\}, |, \&, \sim, 0, 1 \rangle$ forms a “Boolean algebra”
- Or is “sum” operation
- And is “product” operation
- \sim is “complement” operation (not additive inverse)
- 0 is identity for sum
- 1 is identity for product

Boolean Algebra \approx Integer Ring

■ *Commutativity*

$$A \mid B = B \mid A$$

$$A \& B = B \& A$$

$$A + B = B + A$$

$$A * B = B * A$$

■ *Associativity*

$$(A \mid B) \mid C = A \mid (B \mid C)$$

$$(A \& B) \& C = A \& (B \& C)$$

$$(A + B) + C = A + (B + C)$$

$$(A * B) * C = A * (B * C)$$

■ *Product distributes over sum*

$$A \& (B \mid C) = (A \& B) \mid (A \& C)$$

$$A * (B + C) = A * B + B * C$$

■ *Sum and product identities*

$$A \mid 0 = A$$

$$A \& 1 = A$$

$$A + 0 = A$$

$$A * 1 = A$$

■ *Zero is product annihilator*

$$A \& 0 = 0$$

$$A * 0 = 0$$

■ *Cancellation of negation*

$$\sim(\sim A) = A$$

$$-(-A) = A$$

Boolean Algebra \neq Integer Ring

- Boolean: *Sum distributes over product*

$$A \mid (B \& C) = (A \mid B) \& (A \mid C) \quad A + (B * C) \neq (A + B) * (B + C)$$

- Boolean: *Idempotency*

$$A \mid A = A \quad A + A \neq A$$

- “A is true” or “A is true” = “A is true”

$$A \& A = A \quad A * A \neq A$$

- Boolean: *Absorption*

$$A \mid (A \& B) = A \quad A + (A * B) \neq A$$

- “A is true” or “A is true and B is true” = “A is true”

$$A \& (A \mid B) = A \quad A * (A + B) \neq A$$

- Boolean: *Laws of Complements*

$$A \mid \sim A = 1 \quad A + -A \neq 1$$

- “A is true” or “A is false”

- Ring: *Every element has additive inverse*

$$A \mid \sim A \neq 0 \quad A + -A = 0$$

Boolean Ring

- $\langle \{0,1\}, \wedge, \&, I, 0, 1 \rangle$
- Identical to integers mod 2
- I is identity operation: $I(A) = A$
 $A \wedge A = 0$

Properties of $\&$ and \wedge

Property

- Commutative sum
- Commutative product
- Associative sum
- Associative product
- Prod. over sum
- 0 is sum identity
- 1 is prod. identity
- 0 is product annihilator
- Additive inverse

Boolean Ring

$$A \wedge B = B \wedge A$$

$$A \& B = B \& A$$

$$(A \wedge B) \wedge C = A \wedge (B \wedge C)$$

$$(A \& B) \& C = A \& (B \& C)$$

$$A \& (B \wedge C) = (A \& B) \wedge (A \& C)$$

$$A \wedge 0 = 0$$

$$A \& 1 = A$$

$$A \& 0 = 0$$

$$A \wedge A = 0$$

Relations Between Operations

DeMorgan's Laws

- Express & in terms of |, and vice-versa
 - $A \& B = \sim(\sim A | \sim B)$
 - » A and B are true if and only if neither A nor B is false
 - $A | B = \sim(\sim A \& \sim B)$
 - » A or B are true if and only if A and B are not both false

Exclusive-Or using Inclusive Or

- $A \wedge B = (\sim A \& B) | (A \& \sim B)$
 - » Exactly one of A and B is true
- $A \wedge B = (A | B) \& \sim(A \& B)$
 - » Either A is true, or B is true, but not both

General Boolean Algebras

Operate on Bit Vectors

- Operations applied bitwise

01101001	01101001	01101001	
<u>& 01010101</u>	<u> 01010101</u>	<u>^ 01010101</u>	<u>~ 01010101</u>
01000001	01111101	00111100	10101010

All of the Properties of Boolean Algebra Apply

Representing & Manipulating Sets

Representation

- Width w bit vector represents subsets of $\{0, \dots, w-1\}$

- $a_j = 1$ if $j \in A$

01101001 { 0, 3, 5, 6 }
76543210

01010101 { 0, 2, 4, 6 }
76543210

Operations

- & Intersection 01000001 { 0, 6 }
- | Union 01111101 { 0, 2, 3, 4, 5, 6 }
- ^ Symmetric difference 00111100 { 2, 3, 4, 5 }
- ~ Complement 10101010 { 1, 3, 5, 7 }

Bit-Level Operations in C

Operations $\&$, $|$, \sim , \wedge Available in C

- Apply to any “integral” data type
 - long, int, short, char
- View arguments as bit vectors
- Arguments applied bit-wise

Examples (Char data type)

- $\sim 0x41 \rightarrow 0xBE$
 $\sim 01000001_2 \rightarrow 10111110_2$
- $\sim 0x00 \rightarrow 0xFF$
 $\sim 00000000_2 \rightarrow 11111111_2$
- $0x69 \ \& \ 0x55 \rightarrow 0x41$
 $01101001_2 \ \& \ 01010101_2 \rightarrow 01000001_2$
- $0x69 \ | \ 0x55 \rightarrow 0x7D$
 $01101001_2 \ | \ 01010101_2 \rightarrow 01111101_2$

Contrast: Logic Operations in C

Contrast to Logical Operators

- `&&`, `||`, `!`
 - View 0 as “False”
 - Anything nonzero as “True”
 - Always return 0 or 1
 - Early termination

Examples (char data type)

- `!0x41 --> 0x00`
- `!0x00 --> 0x01`
- `!!0x41 --> 0x01`

- `0x69 && 0x55 --> 0x01`
- `0x69 || 0x55 --> 0x01`
- `p && *p` (avoids null pointer access)

Shift Operations

Left Shift: $x \ll y$

- Shift bit-vector x left y positions
 - Throw away extra bits on left
 - Fill with 0's on right

Right Shift: $x \gg y$

- Shift bit-vector x right y positions
 - Throw away extra bits on right
- Logical shift
 - Fill with 0's on left
- Arithmetic shift
 - Replicate most significant bit on right
 - Useful with two's complement integer representation

Argument x	01100010
$\ll 3$	00010000
Log. $\gg 2$	00011000
Arith. $\gg 2$	00011000

Argument x	10100010
$\ll 3$	00010000
Log. $\gg 2$	00101000
Arith. $\gg 2$	11101000

Cool Stuff with Xor

- Bitwise Xor is form of addition
- With extra property that every value is its own additive inverse

$$A \oplus A = 0$$

```
void funny(int *x, int *y)
{
    *x = *x ^ *y;    /* #1 */
    *y = *x ^ *y;    /* #2 */
    *x = *x ^ *y;    /* #3 */
}
```

	*x	*y
Begin	A	B
1	A^B	B
2	A^B	(A^B)^B = A
3	(A^B)^A = B	A
End	B	A

Main Points

It's All About Bits & Bytes

- Numbers
- Programs
- Text

Different Machines Follow Different Conventions

- Word size
- Byte ordering
- Representations

Boolean Algebra is Mathematical Basis

- Basic form encodes “false” as 0, “true” as 1
- General form like bit-level operations in C
 - Good for representing & manipulating sets
